

Preckon

An AI-native construction operating system where every number can name the document, the drawing layer, or the person it came from.

The most consequential number your business produces is the least governed one.

A tender price commits the company for years. It is produced in **two to six weeks**, by one senior estimator, in spreadsheets, from marked-up PDFs — and when it is questioned in a post-tender meeting, the answer comes from memory.

CONCENTRATION

The method lives in one person's head. It leaves when they do.

OPACITY

No trail from a number back to the drawing it was measured off.

LATENCY

The cycle is longer than the bid window, so scope gets thinner.

Every other business-critical number you hold — payroll, ledger, inventory — sits in a system with an audit trail. The estimate does not.

The numbers behind a manual bid.

2–6

weeks for one bid, start to finish

1

person holds the method behind it

0

numbers with a trail back to the drawing

100s

pages of tender read by hand, every time

And the bid window does not move. So the estimator either narrows the scope they price properly, or pads the number to cover what they could not check. Both are expensive, and neither is visible until the job is running.

The preconstruction chain has five stages. Almost every tool owns one.

Everyone sells a stage. The cost, the delay and the lost provenance are all in the joins between them.

Six things that hurt, and what the platform does about each.

THE PAIN TODAY

WHAT IT COSTS YOU

WHAT PRECKON DOES

Reading the tender by hand

Days before real work starts

➡ Extracts requirements and clauses, and structures the bid

Measuring off drawings manually

The single longest task in the cycle

➡ Reads PDF and CAD, measures elements, records a confidence

Rebuilding the bill in spreadsheets

The same rework on every bid

➡ Generates the bill from those measurements, already structured

Chasing rates across email

Inconsistent pricing between bids

➡ Prices from your rate library — every rate names its origin

No trail from number to drawing

Indefensible in a post-tender meeting

➡ Every line carries its source region and who confirmed it

The programme built separately, late

Cost and schedule disagree

➡ Derives the programme from the same bill, deterministically

Every number on screen can tell you where it came from.

Which page of which document. Which layer of which drawing. Or which person typed it, and when they signed for it.

That is the product. The speed is a consequence of it, not the point of it.

It reads the tender first.

Requirements pulled out of the package and tracked as objects — not highlighter marks on a PDF.

The submission format, the deadline and the days remaining are read from the documents, then held as project facts every later stage can use.

Bid decisions — margin, resourcing, health and safety record — sit against the requirements that drove them.

Proposal	Coastal Highway Bridge — Segment 4 — Tender Proposal · 3 sections	CAD 104,080.00	Accepted
Approval pack	Approve for submission — pricing and compliance are in order. · margin 12.5%	CAD 104,080.00	Accepted

It measures, and it shows its working.

Every measurement names the element, the sheet it came off and the location on it — A-101, Grid A-D.

And every one carries a confidence figure. The low ones are the ones you look at; that is the whole point of showing it.

Nothing here is committed. Each row waits on a person to accept the measure.

DRAWLOGIX · TAKEOFF REGISTER

Takeoff register

Quantities measured from the drawings — read from the model above, or extracted from an issued sheet. Check the working before you accept.

All sheets

Measured4

Need review0

ELEMENT	LOCATION	MEASUREMENT	CONFIDENCE	STATUS	
Blockwork external walls A-101	Perimeter	340 m ²	82%	Confirmed	✓ Measurement accepted
In-situ concrete to foundations A-101	Grid A-D	120 m ³	82%	Confirmed	✓ Measurement accepted
Blockwork external walls A-101	Perimeter	340 m ²	82%	Confirmed	✓ Measurement accepted
In-situ concrete to foundations A-101	Grid A-D	120 m ³	82%	Confirmed	✓ Measurement accepted

Every line has a Trace button.

This is the screen the whole product is built around.

A priced bill, grouped by division, units normalised. And on every single line, a button that answers the question estimators normally answer from memory. Press it and you land on the measurement, the sheet and the layer that produced that quantity.

The build-up, not just the total.

Priced bill, overheads, contingency, tender total —
each one adjustable, each one showing what it did to
the number above it.

Rate times quantity equals amount, on every line. And each rate says where it came from: your rate book, history, or a person who typed it.

There is no third category where a number simply appears.

[illegible]

Both fall out of the same bill.

SCHEDULELOGIX · DERIVED PROGRAMME

PROCURELOGIX · PACKAGES FROM THE BILL

The programme is a real critical-path calculation, not a Gantt chart somebody drew. The procurement packages are grouped out of bill lines you already accepted — so the package, the quantity and the price cannot disagree with each other.

Nothing on this screen was committed by software.

Every row is a proposal waiting on a person. Each shows what produced it, what it is about, and how confident it is.

Confirming is a permission — held by a named person, checked at one enforced point in the code.

And each confirmation lands on a tamper-evident chain, against that name and that time.

Not a translated copy. The same workspace.

Right-to-left layout, localised numerals, the same records, the same audit chain, the same permissions.

For a GCC or a bilingual delivery team this is usually the difference between a platform people adopt and one that lives with a single power user.

Six advantages, stated as changes rather than adjectives.

TODAY	WITH PRECKON
A bid takes two to six weeks	➡ The same bid runs in hours, and the estimator spends their time judging rather than measuring
The method lives in one person's head	➡ The method lives in the system, and survives the person leaving
A number cannot be traced	➡ Every quantity names its drawing, sheet and layer
Corrections quietly break things downstream	➡ A correction marks everything downstream stale and tells you what to re-run
Bid capacity is capped by estimator headcount	➡ Capacity is capped by opportunity, not by hiring
A post-tender challenge is answered from memory	➡ It is answered from a tamper-evident chain, in front of the client

Five minutes on the running system.

app.preckon.com — a real tenant, real documents, nothing pre-rendered

BEAT 01 · 60S

Propose

Open a live bid. Run a stage. The assistants read the tender and the drawings and produce proposals — nothing is committed.

BEAT 02 · 60S

Dispose

The review queue. Confirm one, reject one. The bid advances because a human decided, not because a card was dragged.

BEAT 03 · 120S

Correct

They pick a bill line. Trace it to the drawing layer. Then disagree with it — and watch the downstream go stale.

BEAT 04 · 60S

Verify

Trace view, then Verify audit chain, live. Then switch the workspace to Arabic and leave it for a beat.

The commercial model is data. The product plane never learns your contract.

HOST PLANE — CONTROL

Where the product is defined

Feature → Edition → Pricing → Subscription → **resolved entitlements**. Tenant provisioning, billing, platform operations.

32 tables · hash-chained audit · operated by TechSME

TENANT PLANE — WORK

Where the project lives

Projects, documents, drawings, records, review queues, the audit chain.
Consumes exactly **one** thing from the host: resolved entitlements.

84 tables · 90 API routes · deployed

Because the split is that clean, a tenant can be given its own deployment target, its own region, or its own brand without touching product code — and pricing can change without a release.

The core knows nothing about construction.

It knows one interface: `DomainPack`. A vertical is data — one file satisfying the contract, plus a line in the registry.

A pack declares its modules, record types and schemas, assistants with typed I/O, workflows as DAGs, a lifecycle state machine, roles and permissions.

CONSTRUCTION PACK — SHIPPED

8 modules · 18 record types · 20 assistants · 14 workflows · 34 deterministic engines

THE PROOF IT IS REAL

A second pack — **underwriting** — runs on the same unmodified kernel. Construction is loaded, not hard-coded.

THE ABI — FOUR CALLS, NOTHING ELSE

`emitArtifact` · `readArtifacts`

`enqueueJob / onJobResult` · `requestReview`

Every output is a typed record that carries its own parentage.

WHAT PRODUCED IT

The assistant, the model alias, the prompt version, the run.

WHAT IT DERIVED FROM

The upstream records, the document page, the drawing region.

WHO CONFIRMED IT

The named person, the timestamp, the entry on the audit chain.

AND THE PART NOBODY ELSE DOES

Correct a confirmed record and the system keeps its version, records your disagreement against your name, and **marks every downstream record stale** — then tells you precisely what needs re-running. Not the correction. The consequences of the correction.

AI does not own authoritative business state.

Architecture principle P-02, locked as ADR-003. Not a setting. Not a policy document. A structural property of the ABI.

AI PRODUCES

Proposals, extracted facts, classifications, draft records, explanations — each with confidence and provenance attached.

AI CANNOT COMMIT

A bill change. A schedule baseline. A contract value. A drawing revision. An approval. Any authoritative transaction.

Confirming is a **permission**, held by a person, checked at a choke point. Every confirmation lands on the tamper-evident audit chain against a name and a time.

No module ever calls a model.

1	Deterministic software	DEFAULT
2	Exact and semantic cache	BEFORE INFERENCE
3	Structured retrieval	BEFORE LONG CONTEXT
4	Small private model	CLASSIFICATION
5	Private reasoning model	EXTRACTION
6	Frontier model	ESCALATION ONLY

MODEL INDEPENDENCE

Code references aliases — preckon-reasoning — never a vendor. Swapping providers is a registry change.

POLICY BEATS CAPABILITY

A restricted document does not leave its approved boundary because an external model happens to be better at the task.

EVERY CALL HAS ECONOMICS

Attributed per attempt to tenant, project, user, module, route, tokens and cost. AI spend is a product KPI, not an invoice surprise.

A log says what happened. A chain proves nobody changed it since.

AUDIT

Hash-chained

Append-only, tamper-evident, and verifiable from the interface — one button, in front of the customer.

ISOLATION

One choke point

Every tenant-scoped query passes a single enforced path. A cross-tenant read returning zero rows is asserted in the test suite.

PROVENANCE

On every derived value

Source, version, rule and model recorded at the moment of derivation, not reconstructed later.

DURABILITY

State in the database

Jobs, gates and re-plans are durable rows, not in-memory queues. A restart resumes; it does not lose the run.

Integration is a product capability, not a services engagement.

FILES IN

Read once, hashed

PDF · DWG · DXF · IFC · Excel · CSV · P6
XER · images. Ingested once, content-
hashed, and processed revision-aware
so a re-issue costs a diff, not a re-read.

SYSTEMS

Both directions

ERP and accounting · Autodesk and
other CDEs · Primavera · document
platforms · email. Connectors are built
against a published SDK.

API

90 routes, typed

Stable global object IDs, JSON
schemas, idempotent commands,
optimistic concurrency, and
asynchronous jobs for anything heavy.

EVENTS

Outbox, then webhook

DrawingRevised · QuantityChanged ·
BOQChanged · CostImpactDetected ·
SubmittalAffected. Your systems react
rather than poll.

Every export is also how the modules talk to each other internally — which is the reason it has to be complete rather than a retention feature bolted on at the end. **Honest gap: P6 import, calendars and baselines are specified but not yet built.** The critical-path engine underneath them is real and running.

Nothing gets switched off in month one.

PHASE A • NOW

Coexist

Preckon reads and writes against what you already run. It adds a layer and takes nothing away. This is where a pilot lives.

PHASE B

Reduce dependency

Takeoff, the bill, tender workflow, document control and commercial workflows move across natively — one at a time, on evidence.

PHASE C

Native

Preckon becomes the system of work from design through handover, while open exchange with consultants and owners is retained permanently.

Phase A has to earn Phase B. That is a commercial commitment, not just an architectural one.

SHAPE 01

Preckon SaaS

Multi-tenant, managed. Fastest to value, standard terms.

SHAPE 02

Dedicated cloud

Your region, your isolation boundary, our operations.

SHAPE 03

Private AI

Inference inside your boundary. No document reaches an external provider.

SHAPE 04

Sovereign AI

Full on-premise, model serving included, for regulated and state work.

There is no enterprise fork. The same domain model, identity model, API contracts, audit model and AI governance operate across all four. The deployment shape is configuration and hosting — never a second codebase to maintain, and never a second product to certify.

Proven today: SaaS and dedicated cloud. **Supported by the architecture but not yet delivered to a customer: private and sovereign.**

Four things the same foundation makes possible.

HORIZON 1

Beyond the bid

The same chain carries on past award — change control, field capture, quality, handover. The record you built to win the job becomes the record you run it from.

HORIZON 2

Beyond one project

A typed graph across every project: rate history, productivity, which risks actually materialised. Your own portfolio becomes the benchmark you price against.

HORIZON 3

Beyond construction

The kernel is domain-neutral. Construction is one pack; underwriting already runs on the same core. A vertical is data, not a rewrite.

HORIZON 4

Beyond one company

Open exchange stays permanent. Consultants, owners and subcontractors keep their own tools — the chain does not require everyone to adopt it.

The moat is not the construction pack. It is that the pack is data, sitting on a kernel that could carry another industry.

132 features. 97 done, 15 partial, 20 missing.

Measured against the blueprints *as written* — 13,074 lines of specification across ten documents. Not against a roadmap we could move.

HOW IT IS COUNTED

Done means built, tested and deployed. Partial counts as a half. Missing counts as zero. Every row verified against the codebase and the deployed production database.

These were queried from the repository and the running production database on the morning of this briefing. Any of them can be re-run in front of you.

ENTERPRISE REQUIREMENT	STATE	NOTE
SSO — SAML / OIDC	NOT BUILT	Deal blocker. Named in the platform spec.
MFA	NOT BUILT	Deal blocker.
Encryption at rest + KMS	NOT BUILT	Specified, not yet implemented.
CI running the suite	0 RUNS	Six workflow files exist; none has executed.
Staging environment	NONE	Changes are validated in production.
Backup with tested restore	NONE	An untested restore is not a backup.
Retrieval / RAG	PARTIAL	Wired for DocLogix; no embeddings yet.
AI policy enforcement	REPORT-ONLY	Recording on every call; enforcement behind a flag.

Sixteen open P0s. These are the eight you would have found.

You will find every one of these in a diligence pass. We would rather you heard them from us, in the room, than from a consultant in week six.

The trust foundations underneath — audit chain, tenant isolation, provenance, durable jobs — are built and tested. What is missing is the enterprise *operations* layer around them. A known, bounded, unglamorous list.

Three things, six weeks, one live tender.

- 01 **One real bid, end to end.** One project, one estimating team, six weeks — measured against a bid you have already priced, so the comparison is yours and not ours.
- 02 **A golden set.** One design set paired with its final priced bill, which we hold as a regression fixture. Accuracy stops being a claim the moment it has a fixture behind it.
- 03 **A named security counterpart.** Someone on your side who closes that P0 list with us inside the same six weeks — SSO, MFA, CI, staging, backups.

WHAT WE ARE NOT ASKING FOR

A migration. A system to be switched off. A commitment beyond the pilot. Or a decision today.

Twenty minutes. From an empty project to a priced bill, a programme, a technical submission and a register of what is still outstanding.

But the number of minutes was never the argument.

Every number you saw today can name where it came from. A page of a tender, a layer of a drawing, or a person who typed it and signed for it.

That is the whole product. The rest is speed.
